

Russian Inequality on the Eve of Revolution

PETER H. LINDERT AND STEVEN NAFZIGER

Careful handling of an eclectic data set reveals how unequal were the incomes of different classes of Russians on the eve of Revolution. We estimate incomes by economic and social class in each of the fifty provinces of European Russia. On the eve of military defeat and the 1905 Revolution, Russian income inequality was middling by the standards of that era, and less severe than is inequality today in China, the United States, and Russia itself. We note how the interplay of some distinctive fiscal and relative-price features of Imperial Russia might have shaped the now-revealed level of inequality.

Just how unequal were the incomes of different classes of Russians on the eve of Revolution? We provide detailed income estimates for economic and social classes in each of the fifty provinces of European Russia. In 1904, on the eve of military defeat and the 1905 Revolution, Russian income inequality was middling by the standards of that era, and no more severe than inequality has become today in such countries as China, the United States, and Russia itself. The interplay of some distinctive fiscal and factor-endowment features of Imperial Russia shaped the now-revealed level of inequality.

ISSUES AND OVERVIEW

After the emancipation of the serfs in 1861, Tsarist Russia's pace of industrial development, urbanization, and economic growth accelerated. Despite these changes, Russian society was riven by formal social, political, and class divisions, which observers have long tied to the revolutionary events of the early twentieth century. However, for all the debate over class differentiation in Russia before the Bolshevik

This article presents results from an open-source research project. As much as possible, the data are being posted on <http://gpih.ucdavis.edu> (click on the main data list folder, scroll to Eastern Europe). We thank the U.S. National Science Foundation for support under grants 0922531 and 1227237, and acknowledge the helpful comments of participants in the March 2011 conference on "Quantifying Long-Run Economic Development" at The University of Warwick in Venice, and at the World Economic History Congress in Stellenbosch, July 2012. Aaron Seong, Stefan Ward-Wheten, and Nikolas Zolas provided excellent research assistance.

Revolution, scholars have yet to develop a comprehensive measure of the country's level of inequality. This has not been due to a lack of attempts, as a number of writers have endeavored to describe how income and wealth were allocated in Tsarist society.

Russian and Western scholars have long drawn on simple measures of asset ownership to document inequality through the lens of "class differentiation." However, their indicators, such as the number of horses, the amount of land, or the number of wage earners cover are only a subset of all assets, are only indirect measures of income, and were typically drawn from limited empirical sources for a specific geographic area. Such measures cannot reliably approximate the true distribution of income or wealth in Tsarist Russia. As a result, although Paul Gregory (1982), Peter Gatrell (1986), and others have identified a fairly high rate of economic growth in the last decades of the Tsarist regime, we know very little about how such gains were distributed among the population. The lack of a clear depiction of the level of Russian inequality not only limits our understanding of the roots of the 1905 and 1917 revolutions, but it also impairs our accounting of the evolution of the Russian economy over the period.¹

This article helps to fill this gap by drawing on newly compiled provincial and social estate-level data on high income earners (those earning more than 1,000 rubles, which was about 1.6 times the income of an average household of 5.8 persons), on wages in a variety of occupations, and on both communal and private land holdings for a small window around the year 1904. We use this information to derive estimates of income inequality in the late Tsarist period at the provincial level and for European Russia as a whole. We provide both Gini coefficients and income shares to document pre-tax income inequality and polarization for this benchmark year, which we then compare to existing estimates for the Soviet Union, post-Soviet Russia, and other historical economies at various points in the development process.

Our findings—which we subject to a variety of robustness exercises—suggest that just prior to the revolutions of the early twentieth century, Russia's income inequality was not exceptional, either in comparison to contemporary societies or when stacked up against estimates for the post-Soviet period. This was despite the extreme suppression of political rights, the inequality of landownership, and the clear regressivity of the imperial fiscal system. We suggest that this "moderate" income inequality was a net result of the tension between Russia's labor scarcity, or land abundance, and its regressive

¹ Gregory (1982, p. 146), himself, notes the lack of adequate research on inequality in Tsarist Russia.

and repressive institutions. At the same time, inequality was higher in the capital city provinces, the Baltics, and the Black Sea region—i.e., some of the more dynamic and urban parts of the empire. As the revolutions of 1905 and 1917 were urban in origin, the geography of Russian inequality would suggest some support for distributional factors as underlying causes. However, our picture is just a snapshot. Additional research on the dynamics of inequality is necessary before more definitive accounts of the role played by economic processes in the two revolutions can be drawn.

PRE-REVOLUTIONARY INEQUALITY: SOURCES AND INTERPRETATIONS

Inequality in Tsarist Russia has received remarkably little quantitative attention.² This has mainly been due to data constraints. No representative income or wealth surveys were undertaken across different sectors at any point in time. As noted, measures of inequality or differentiation frequently took the narrow form of livestock, land, or other asset distributions across exclusively peasant households, often only in small geographic areas.³

After 1861 academics and policymakers were increasingly aware of the limits to their knowledge of the countryside, and of economic conditions in the empire more broadly. As a result, the Central Statistical Committee of the Ministry of the Interior and other ministerial bodies sponsored numerous statistical research projects, culminating in the first national census in 1897. The census not only documented the ethnic, religious, and geographic diversity of the empire, but it also collected detailed data on the occupational structure of the population. This census and other similarly impressive efforts after 1900 (such as the 1905 Land Statistics) provide some of the necessary building blocks for estimating the level of inequality in European Russia around the turn of the century.⁴ But few scholars have

² Allen acknowledges this point (2004, p. 37, note 10). A search for the terms “income” or “wealth,” “inequality” or “unequal,” and “Russia” or “Soviet” in the database Historical Abstracts turned up practically no relevant entries and exactly none that pertained directly to the late Tsarist period. On inequality in the Soviet Union, see Bergson (1984) and McAuley (1979).

³ Harrison (1977) and Merl (1990) provide excellent accounts of these methods and of how later scholars continued to draw on populist and Leninist models in documenting peasant differentiation.

⁴ Scholars have generally viewed the 1897 Census as relatively well done for its time and context, but the published data likely do include some significant errors in the reported age structures and urban population totals (Rowney and Stockwell 1978). Given our methodology, we feel that such errors probably have little impact on our findings, assuming they occurred randomly across the country. The 1905 Land Statistics have been widely used in aggregate form, although the present article is one of the first to rely on data built up from the district

endeavored to evaluate just how unequal Russia was by 1900, and those that did so have generally relied on approaches that do not compare well to modern estimates.

Two literatures emerging at the end of the nineteenth century indirectly spoke to the nature of inequality in late Tsarist society. The first was the rise of a school of populist peasant studies that built upon and extended *zemstvo* research by undertaking detailed budget studies of “representative” peasant households.⁵ Emerging first in the province of Voronezh under the leadership of Feodor Scherbina in the 1880s (e.g., Scherbina 1897), this movement later came to be associated with the work of Alexander Chaianov, especially his influential *The Theory of the Peasant Economy* (1986). According to this line of scholarship, inequality of rural households was driven more by life-cycle events such as aging or household divisions than by broader social forces.

Such budget data and *zemstvo* studies of rural households also played a key part in a second literature: Soviet interpretations of peasant *differentiation*, or *rassloenie* (or “polarization”), into rich *kulaki* and a poor, increasingly landless, rural proletariat (e.g., Anfimov 1984; Rashin 1950). Field’s (1989) fascinating analysis of turn-of-the-century wealth polarization among the peasants of agricultural Poltava and other provinces builds on these two literatures by estimating Gini coefficients (and their change over time) for different agricultural assets.⁶ According to this research, agricultural assets were held relatively unequally, even among the supposedly homogenous peasantry. Similarly to contemporary observers who asserted that “differentiation” was growing over time, Field emphasizes the emergence of “rural capitalism” among the peasant population by 1900. However, he also acknowledges that such *zemstvo* data make it difficult

(*uezd*) level. The Central Statistical Committee, with the help of provincial statistical bureaus and various local officials, collected these data from (property) tax registers and other sources (Russia, Tsentral’nyi, 1906, vol. 51, Intro).

⁵ The *zemstvo* was a new institution of local self-government established in 1864 in most of European Russia following the emancipation of the serfs (Nafziger 2010, 2011). Many district and provincial *zemstvo* created statistical research bodies to collect data and monitor the taxable resources under their jurisdiction. Most of these efforts tended to focus on land and other assets (for examples, see Svavitskaia and Svavitskii, eds., 1926), rather than income or household budgets, and some scholars have been critical of the motivations and conclusions of the *zemstvo* researchers (e.g., Darrow 2002). However, there is no evidence that the raw household and village-level data were biased to any significant degree.

⁶ Chapter 2 of Lenin (1974)—and subsequent Soviet works—provides a series of tables that classify peasant households into strata depending on land, livestock ownership, and some limited budgetary information for a small number of districts for which he had access to *zemstvo* surveys. In some cases, Lenin just took the classifications from the underlying *zemstvo* statistics, while in others he derived the groupings himself. Field (1989) uses similar data, but takes the existing *zemstvo* categorizations and derives Gini coefficients. We present a number of such estimates from Field and others in the Online Appendix.

to accurately estimate true income or wealth inequality, because the asset categories, definitions of a household, and types of peasant economic activity changed over time and differed across surveys.⁷

Two other areas of scholarship also relate to our method of calculating income inequality. The first is the literature on living standards in Tsarist Russia. Soviet scholars such as Iu. I. Kir'ianov (1979) tended to focus on *either* rural or urban (i.e., “worker”) living standards by considering work conditions, diets, and some very limited information on wages and salaries. These studies were written through a Marxist filter and, therefore, did not pay much attention to the income generated from asset ownership. In his recent impressive work on living standards from Peter the Great to the Revolution, Boris N. Mironov (2010, 2012) quickly sets aside direct calculations of incomes (and their distribution) in favor of an anthropometric approach. His reliance on military and factory data on adult heights opens an important area of research into Russian living standards, especially over time, but it does not directly measure economic inequality.

Second, many Soviet and post-Soviet studies of living standards, peasant stratification, the emergence of a working class, and household budgets have tended to be micro in their use of evidence. Indeed, we argue elsewhere that micro studies of living standards are valuable for understanding the nature of heterogeneity in Russian living standards (Dennison and Nafziger 2013). However, evaluating the level of inequality in a particular society requires taking a more aggregate approach. Paul R. Gregory's (1982) important revision of Russian national income—which documents a relatively high growth rate from the 1880s to 1913—provides a baseline measure of the size of the economic “pie” that was divided among agents in the economy. In the process of compiling these accounts, Gregory makes a rough calculation that the top 1 percent of earners received about 15 percent of national income around 1904 (Table 1).⁸

⁷ In a more recent work, Johnson (1997) analyzes income stratification by household size, as reported in a 1909 budget survey from Kostroma province. He emphasizes the existence of Chaianovian life-cycle differences in household wealth and inequality, but his study refers to a small sample and a limited geography.

⁸ This calculation relies on the same source of high incomes that we employ below. In a related work, Gregory (1980) estimates aggregate peasant grain consumption but does not look into the consumption of foodstuffs of urban or non-peasant populations. Early Soviet studies of national income prior to 1913—particularly Prokopovich's (1918) estimates for 1900 and 1913—did emphasize some geographic inequality that Gregory does not explore. Markevich and Harrison's (2011) recent study of revolutionary era growth accepts Gregory's pre-1913 income estimates, while arguing for a sharper decline after 1917.

Our brief summary of the literature on inequality in pre-Soviet Russia points to a simple fact: there has been little comprehensive work. For the Post-Revolutionary era, more extensive data on earnings do enable broader measures of the distribution of incomes, including 90/10 percentile ratios and Gini coefficients for the entire USSR.⁹ Estimates of pre-1917 inequality focused on small parts of total income and did so for small geographic areas (often limited by the scope of individual *zemstvo* research efforts). Assignment of households to income strata was generally done by asset ownership, although returns from owning these assets rarely entered into early calculations.¹⁰ In what follows, we rely on a variety of sources and a new methodology that allow us to estimate overall inequality around 1904 in a way that is comparable to methods used for other societies at different points in time.

PUTTING HOUSEHOLDS INTO SOCIOECONOMIC GROUPS

Choosing Households as the Population Unit

This article focuses on the household as the relevant population unit for income distribution for two reasons, one theoretical and one practical. Simon Kuznets emphasized the theoretical primacy of the household in the 1960s and 1970s. He warned repeatedly that studies of inequality often fail to define the unit of population clearly.¹¹ The usual candidates are:

- inequality of total income among households
- inequality of income per household member (or per adult male equivalent)
- inequality of individual incomes per economically active person (e.g., taxpayer, or member of the labor force)

For Kuznets, caring about economic inequality means caring about how unequally people consume resources over their lives. For him, one must measure annual household income per consumer in the household because households share their resources. The income numerator must capture the incomes of all economically active

⁹ See a representative sample of estimates from Bergson (1944 and 1984) and McAuley (1979), as presented in the Online Appendix.

¹⁰ That communal allotment land (*nadel'naia zemlia*) comprised the bulk of property held by most peasants has led many scholars to assume more homogeneity among peasant households than was likely true in practice. Soviet class-based analyses did not necessarily make this assumption, but many did tend to assume that the possession of little property was equivalent to low incomes.

¹¹ See especially Kuznets (1976).

household members, and the population denominator should capture the number of adult-equivalent consumers. He warned against measuring inequality among individual earners.

Kuznets's theoretical argument is reinforced by the constraints inherent to Russian data. Our Imperial Russian sources favored studying households (*dvory* or *khoziaistva*) as income recipient units especially for the peasantry.¹² Throughout European Russia, the peasant commune assigned land and tax obligations to households; inheritance, political authority, and demographic practices were channeled through such units (Worobec 1995). Those who investigate the income structure of other countries in centuries past also focus on households, since they too confront the simple fact that taxable property, such as real estate, tends to be used by, and assigned to, all household members together, even if only one member is the owner and taxpayer.

Estates and Sectors

Imperial Russian law and social inquiries helpfully classified households into groupings useful for our pursuit of income differences. First, across the four centuries leading up to the 1917 Revolution, imperial officials defined classes in a way that differentiated them clearly by legally distinct social estates (*soslovia*). Our reading (and analysis below) suggests that these categories tended to correspond to income levels, with modifications for urban/rural residence and occupation. This makes it relatively straightforward for us to divide national income along the same class lines that others have considered important. True, the classes overlapped in their income distributions to some extent, but there is considerable evidence that the social tables based on mean incomes for socio-occupational classes come close to approximating size distributions of households' income.¹³

Therefore, we need accurate social tables for late Imperial Russia. Mironov (2010) has documented membership in estate classes

¹² Both *khoziaistvo* and *dyor* are terms used to refer to households in our time period. Information on the variation in household size across European Russia is very limited. The method of reporting of the 1897 Census makes it difficult to document differences between provinces without additional assumptions. Rynziudskii (1983, pp. 22–23) reports somewhat larger households in the Ukrainian and Southern provinces, while Worobec (1995, p. 104) argues that household size was relatively constant at around 6 in the central region. We assume that the number of earners was constant across European Russia. We have experimented with relaxing this assumption, but our aggregate inequality estimates are little affected.

¹³ Milanovic, Lindert, and Williamson (2011) note how historical tables of class average incomes seem to approximate size distributions in many countries. Wirtschafter (1997) provides a valuable discussion of *sosloviia*, including how their characteristics overlapped by the end of the nineteenth century.

TABLE 1
THE SOCIAL STRUCTURE OF EUROPEAN RUSSIA, 1858–1913

Estate (thousands of persons)	1858	1870	1897	1913
Nobility	889	861	1,373	1,936
Hereditary	612	544	886	1,249
Non-hereditary	277	317	487	687
Clergy (Christian)	567	609	501	697
Military	3,767	3,981		
Army	927	704	1,095	1,320
Honored, titled	21		308	611
Merchants	400		240	
Urban	4,300	6,091	10,493	22,716
Peasantry	49,000	53,600	80,100	103,300
<i>Raznochintsy</i> (“different ranks”)	730	383	738	258
<i>Total population</i>	59,300	65,500	93,200	128,900
Percent Shares of Total Population				
Nobility	1.6	1.4	1.5	1.5
Clergy (Christian)	1.0	1.0	0.5	0.5
Army	1.6	1.1	1.2	1.0
Urban	7.6	9.8	11.1	17.4
Peasantry	86.9	86.1	84.9	79.3
Other	1.3	0.6	0.8	0.2
<i>Totals</i>	100.0	100.0	100.0	100.0

Notes: The top part of the table indicates the number of people in households headed by individuals in the designated social estate. These data are compiled in Mironov (2000, p. 254) and revised in Mironov (2010, p. 645). The totals in 1913 are reconstructed from church administrative data (1895–1914) and the agricultural census of 1916. The totals for other years are from population and tax-related censuses. The number of “Honored, Titled” (*pochetnye grazhdane*) households in 1870 are unavailable, while the number in 1913 includes the merchant class. In general, this estate included the higher strata of the urban population, along with upper-level clergy. The “Urban” estate, therefore, included the remaining urban population. Data on the full number of military households are incomplete for 1897 and 1913.

since 1678; his findings are summarized in Table 1. Despite signs of urbanization and churning at the top, with the replacement of old aristocracies with new, changes were slow. The shares of the aristocracy, defined by hereditary or granted title (including attainment via promotions up the famous Table of Ranks), were not high, hovering at less than 2 percent of the population of recognized households.¹⁴

¹⁴ From Peter the Great until the end of the regime, the social structure of the elite in Imperial

That was perhaps comparable with the early modern share in France and England. *Ancien regime* France in 1780 had a similar share of its population distinguished by nobility or clergy: 1.93 percent. For England and Wales, the share distinguished by landowner status was similar, but a bit higher 3.47 percent in 1801–1803.¹⁵ While these are only rough counts, it is noteworthy that a far more rural Russia had such a small share of its population in the landed elite. As Table 1 indicates, the share of the population in the nobility was small and stable from 1858 to 1913.

To this stable and skewed social structure, we can attach household counts by economic sector for 1897 (and project forward to match income data for 1904). We attach data on earnings to different parts of the population using the sector that the household head worked in. We count households in the main output sectors by starting with the 1897 census estimates of sectoral occupations (*zanyatie*) of household heads and inflating the counts to 1904 using population data from the 1904 statistical yearbook of the Ministry of the Interior.¹⁶ Combining the occupational-sectoral (*zanyatie*) household counts with the social estate (*soslovie*) household counts (all by province in European Russia) generates the basic structure underlying the income distribution. Knowing the sector helps to identify the greater earnings of peasants working in industry or local government than those in agriculture or domestic service. And knowing the estate helps to delineate those in “industry and commerce” who were peasants from those in “industry and commerce” who were of the merchant estate. In practice, we began with agriculture and proceeded through the output sectors, ending with industry and commerce as a residual. For each sector, we drew upon the 1897 Census data to allocate households across sectors sequentially, social estate by social estate, for rural and urban areas in each province. We then scaled up the numbers of households according to province-specific population growth between 1897 and 1904.¹⁷

Russia was distinguished by its Table of Ranks, which translated civil and military service into noble status. For the traditional landed elite families, noble social status was passed down as part of the estate. Above a certain achieved rank for others in the civil or military services, any granted noble status also became hereditary.

¹⁵ See Morrisson and Snyder (2000) on France in 1780, Lindert and Williamson (1982) on England 1688–1803.

¹⁶ The 1904 population totals—taken from Russia, Tsentral’nyi (1905)—are not exact figures. Rather, they reflect rough counts (based on the 1897 Census) that were maintained for fiscal purposes. Although the resulting numbers (and the population changes from 1897 that we derive) may slightly misallocate people across rural and urban areas, we doubt that the scale of such error was large or that it would significantly bias our results, given the presumed accuracy of the 1897 population allocation across provinces.

¹⁷ The Online Appendix provides additional details (and the final totals) regarding

TABLE 2
HOUSEHOLD HEADS BY ECONOMIC SECTOR IN EUROPEAN RUSSIA, C. 1904

	Thousands of Households			%
	Urban	Rural	Total	
Agriculture (<i>sel'skoe khoziaistvo</i>)	198.9	13,522.5	13,721.4	75.0
Mining	4.5	75.6	80.1	0.4
Manufacturing	572.9	868.5	1,441.4	7.9
Construction	97.8	184.6	282.4	1.5
Trade, transport, communications	504.6	492.1	996.8	5.5
Administration (government)	81.0	57.7	138.7	0.8
Clergy	30.9	95.1	126.0	0.7
Free professions	67.5	54.8	122.3	0.7
Private service, servants &c	321.2	453.1	774.3	4.2
Other	318.1	283.5	601.6	3.3
<i>Total households</i>	2,197.3	16,087.6	18,284.9	100.0

Note: These data are from Troinitskii, ed. (1905, vol. 8) and Russia, Tsentral'nyi (1905).

In the end, we construct 2,300 income-earning groups (23 estate-sector combinations by fifty provinces, and by urban versus rural), even before later stratifying by income level on the basis of additional data.

In output sectors as in social classes, Russia's distribution of households was quite skewed: rural agriculture accounted for the lion's share of the population (see Table 2).¹⁸ By itself, the dominance of agriculture and the peasantry might have obscured our view of overall differences in income. Fortunately, however, we can turn to sources that document high-income earners by sector and social class, the level and inequality of agricultural landownership (and income) by social class, and detailed decompositions of peasant incomes across different sectors. For our study, as for most other quantitative studies dealing with the pre-Revolutionary period, data constraints limit our measures to the fifty provinces of European Russia, omitting Finland, Poland, Transcaucasia, Central Asia, and Siberia.

our assumptions about which estates tended to combine with which output sectors, with further separation by rural versus urban residence.

¹⁸ See Appendix Table 2 in the Online Appendix.

FOLLOWING THE INCOME CLUES FOR 1890S–1905

Incomes from Landownership

Our best opportunity to take a snapshot of the Russian income structure comes from around the turn of the twentieth century, especially from a combination of large data sets stretching from 1897 to 1905. To work these data sets into a single estimate for “1904,” we start with the generous data on land ownership as of 1905, courtesy of the same Central Statistical Committee that gave us Imperial Russia’s 1897 Census.¹⁹ The 1905 survey measured landownership by the size of area owned, by county and province, and by estate of owner. The estate-of-owner detail is also rich, which is critical given the complexity of Russian land institutions. The data delineate individual household owners by six social estate classes—aristocracy, clergy, merchants and esteemed citizens (*kuptsy i pochetnye*—the latter was comprised mostly of urban titled elite), townsmen (*meshchane*), peasants, and miscellaneous estates including foreign individuals. There are separate totals for different types of collective landownership, including peasants’ shared allotment (*nadel’nye*) land stemming from the 1861 emancipation, state lands, corporate lands, and other categories.

The rich detail of the 1905 land survey is subject to two drawbacks for our purposes, drawbacks that we can partly offset with other data. First, the survey consolidated the different holdings of each individual landowner only within each district, without connecting the properties of the same landowner in different districts or provinces. Fortunately, the data impose enough structure to demonstrate that the merging of individual landed properties across provinces cannot have affected income inequality very much. What might seem like a potentially huge understatement of landed inequality cannot be very large, given how certain totals by province and by top income class constrain the possibilities.²⁰ In particular, the amount of a district’s land, or rental income from owning land, that could, at most, be reallocated to owners from *other* provinces (remember, all of our estimates are originally undertaken at the provincial level) was actually quite limited and would

¹⁹ The “land” surveyed in 1905 appears to exclude urban real estate as strictly defined, or so we gather from the juxtaposition of the two kinds of assets (urban and rural real estate) documented in Russia, Ministerstvo (1906). This exclusion might not be evident from the 1905 land survey by itself, since it included both the “urban” and “rural” divisions of each province in some categories. Yet, as other scholars have noted, the officially urban parts of each province contained agricultural lands. We compiled our data from the district-level up using the fifty provincial volumes of Russia, Tsentral’nyi (1906).

²⁰ We briefly discuss this here and provide evidence of the robustness of our results to the separation of land data by district in the Online Appendix.

have only marginal implications for the inequality of landed income. This is because hypothetically “adding” additional land to one large landowner’s holdings would entail taking it away from another, likely equally large, owner. We are also aided by our knowledge of the social estate of landownership, which prevents us from misattributing ownership across estates within a province.

A second drawback of the 1905 land survey is that it presents data only on the land areas owned, and not their annual rental value. Fortunately, the Finance Ministry’s 1906 study *Opyt’ priblizitel’no ischislenia narodnovo dokhoda po raslichnym evo istochnikam i po razmeram v Rossii* [hereafter *Opyt’*] provides average rents in rubles per *desiatina* (approximately 2.7 acres) per year for each province. We use their provincial rental rates that assumed a 6 percent return on purchase value and that all lands in each province had the same value.²¹ We thus capture only the differences in value per *desiatina* across provinces, not those within provinces.

The distribution of private landownership, as shown in Table 3, departs from any simple separation of landed from landless social estates. Only one-third of the nobility (*dvorianstvo*) consisted of landowners, and over a fifth of all merchants and esteemed citizens owned land outside the cities. Of course, of those closest to the land, the peasantry, fewer than 4 percent of household heads had individual privately owned land. This distribution of rural private landownership, by itself, makes Russia look very unequal in international perspective. Table 3’s data show that only 4.7 percent of households owned private (non-communal) land other than the plots under urban buildings. This ownership share is smaller than that of other data-supplying countries in the late nineteenth and early twentieth centuries, with the possible exception of Mexico.²²

This high level of land inequality—and its limited geographic variation—is depicted in Panel A of Figure 1. Not only is the overall Gini coefficient of purely individual holdings high (0.88), but the range is rather narrow across provinces: aside from Archangel’ province’s Gini of 0.05 (due to the small number of exclusively peasant owners), the next lowest coefficient was 0.55 in the Don Cossack Lands, and the remainder were above 0.63. Significantly, land inequality is lower if

²¹ The *Opyt’* study (Ministry of Finance, 1906) also gave alternative rental rates by province, not assuming a 6 percent return. Our results when applying these rates are similar in all qualitative respects. Despite residual legal distinctions between the two types of property, other work (e.g., Nafziger 2010) suggests that the peasantry faced relatively integrated communal and private land rental markets by 1904, especially when it came to smaller plots.

²² For the other countries, see Lindert (1987, p. 39, table 1).

TABLE 3
LAND RENTAL INCOMES OF INDIVIDUALS IN EUROPEAN RUSSIA, 1905

Estate	Households (1,000s)	Owners (1,000s)	Percent Owning	Land Rents (1,000s r.)	Percent of All		Rent per Owner
					Owners	Rents	
Nobility	265	88	33.2	247,334	10.2	39.3	2,813
Clergy	99	8	8.6	3,995	1.0	0.6	473
Merchants	106	23	21.2	59,086	2.9	9.4	2,630
Townspeople	1,950	85	4.4	42,420	9.8	6.7	500
Peasants	15,435	622	4.0	262,482	72.1	41.7	422
Misc., foreign	430	38	8.7	14,440	4.4	2.3	384
<i>Total</i>	18,285	864	4.7	629,757	100.0	100.0	729

Note: The figures exclude urban realty. In addition to their individual private holdings, the same estates held land as shares in collective private property holdings, amounting to about 12.3 percent of all private land area. These are included in the totals here. Most of this was held by the peasantry. A large share of the peasantry held shares of communal allotment land (*nadel'nye zemli*), generating an estimated 447,858,172 rubles in rental incomes. Merchants &c = merchants and esteemed citizens (*kuptsy i pochetnye*).

Sources: The sources of these data are the owners and land areas from the 1905 Land Census (Russia, Tsentral'nyi, 1906); and rent information from Russia, Ministerstvo (1906). For the derivation of these estimates, see the file, "Ownership of rural lands 1904 (Nafziger-Lindert)" at <http://gpih.ucdavis.edu>, under Russia in the main data list.

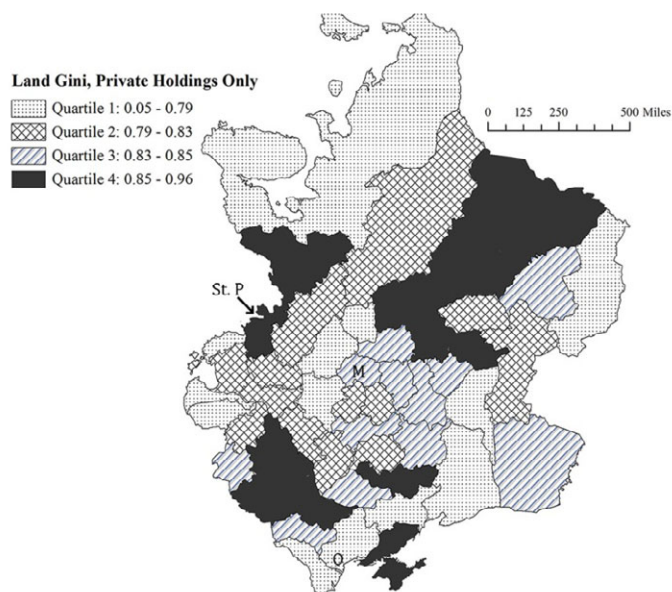

we add peasants' communal land holdings per household (Panel B of Figure 1), although the overall Gini remains high at 0.60.²³ Yet, as we shall see, Russia's high land inequality does not translate into internationally extreme levels of total income inequality.

Peasant Incomes

We are fortunate that pre-Revolutionary officials, *zemstvo* researchers, and scholars took seriously the task of learning not only the averages, but also the distribution, of peasant assets and, very occasionally, incomes in a large number of provinces between the 1880s and the early 1900s. Scholars such as David W. Darrow (2002) and Igor Khristoforov (2011) have been critical of the methods and perceived lack of objectivity among *zemstvo* statisticians, but their views generally refer to the researchers' conclusions rather than the raw data. Robert E. Johnson (1982 and 1997) and Steven Nafziger (2010) have pointed out that, in practice, the asset and budget data collected by *zemstva* and other statistical bodies appear representative.

²³ Particularly high levels of land inequality are evident in St. Petersburg, right-bank Ukraine, the Urals, and the southern New Russian provinces.

Panel A.

Panel B.

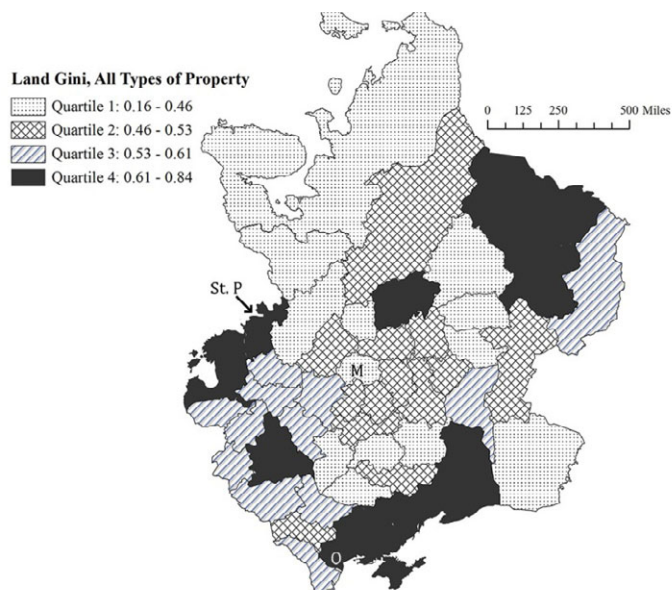

FIGURE 1
 THE GEOGRAPHY OF LANDHOLDING INEQUALITY, C. 1905

Notes: The underlying land data are taken from Russia, Tsentral'nyi (1906). Panel A indicates inequality across only private holdings. In Panel B, the Gini are calculated across all types of land holdings, including peasant shares of communal land. "Ownership" in both measures is limited to the district—i.e., estates that spill across more than one district would be counted as separate properties for these province-level calculations. As reference points, St P = St. Petersburg, M = Moscow, O = Odessa (in Kherson Province).

Therefore, to more fully document the income distribution of the roughly 80 percent of the population who were peasants, we make use of the results from several *zemstvo* surveys, supplemented by the 1905 land returns and by independent data on local wage rates.

The heterogeneity of our source materials calls for some elaborate procedures to differentiate peasant income experiences within one province, and then to extrapolate across provinces.²⁴ Our starting point is the large budget survey of peasant households in Voronezh in 1897 (published in Shcherbina 1900). This provided distributions of incomes by landowning categories that we extrapolated to 1904 ruble values using the aggregate trend in nominal incomes (from Gregory 1982).²⁵ Our extrapolation from Voronezh to other provinces then uses other provincial *zemstvo* studies of peasant incomes, plus relative wage rates in agriculture and industry and the detailed 1905 landownership data for the small share of (private) landowning peasants in each province. The resulting estimates, aggregated to the level of European Russia, appear in Table 4.

A feature of Russia's peasantry that stands in contrast to most other countries' agricultural or rural households before 1914 is that most of the Russian peasantry were effectively "tenant" farm operators and their dependents. Fewer than 5 percent of peasant households were laborers who lacked their own farm, just as fewer than 5 percent owned land *only* as individual households (i.e., non-*nadel'naia*, or non-communal, land). What we call "tenants" were those peasants who received agricultural income primarily from the application of labor to production on their share of communal holdings.²⁶ This broad group was fairly compressed in its income levels, with the top 5 percent (the "top farmer operators, not private owners" in Table 4) having only a bit more than triple the average incomes among the bottom quarter ("lower farm operators"). Part of the reason, of course, is that collectively owned land, whose value is included in these measures,

²⁴ These procedures—and the additional sources that we rely upon—are spelled out in greater detail in the Online Appendix. Here we simply note the general procedural steps.

²⁵ We started with the Voronezh survey due to its apparent completeness, timing, extensive use by other scholars (e.g., Wilbur, 1983), and comparability to studies in other provinces. Detailed budget studies are relatively few before 1905. Despite the agricultural focus of the Voronezh peasantry, we allowed the amount of nonagricultural income to vary by province based on other data sources (see the Online Appendix). We have explored using the budgetary data from other, lower quality, *zemstvo* peasant surveys, with little impact on our overall findings. Finally, as a recession in 1900 and 1901 set industrial development back, we feel that the occupational distribution in 1897 is a decent approximation for 1904.

²⁶ This is slightly non-standard nomenclature, but we feel that it reflects the way collective ownership and obligations functioned in practice.

TABLE 4
ESTIMATED PEASANT HOUSEHOLD INCOMES IN EUROPEAN RUSSIA, C. 1904

	Households (1,000s)	Total Incomes (1,000 r)	Income per Household
<i>Households with Shares of Communal or Other Collective Holdings</i>			
Poor farmless laborers (land = 0)	687.9	152,096	221
Lower farm operators	3,770.8	1,199,049	318
Middle farm operators	7,117.8	2,894,742	407
Upper farm operators	2,569.3	1,442,951	562
Top farmers, not private owners	737.8	712,283	965
<i>Households with Privately Owned Property</i>			
0 < 1k	543.2	591,033	1,088
1k–2k	4.6	11,186	2,413
2k–5k	2.6	10,840	4,135
5k–10k	0.7	6,017	8,087
10k–20k	0.3	4,053	14,794
20k–50k	0.1	2,445	29,939
50k–up	0.008	897	116,456
<i>Totals</i>	15,435.3	7,027,591	455

Notes: “Poor farmless peasant laborers” is our estimate of households residing in communal villages but without a share of allotment land. The individual peasant landowners of Table 3 included the private landowners described here and some non-communal but collective land holders. The source for the 1897 population and household counts by sector is Troinitskii, N.A., ed. (1905, vol. 8), with population adjustments according to growth rates calculated with the aid of Russia, Tsentral’nyi (1905, pp. 40–53). Underlying data on wage incomes in the 1890s are from *zemstvo* budget studies reported in Russia, Departament (1903, p. 199 and pp. 234–37). *Zemstvo* studies tended to average incomes per peasant household for particular areas. Such studies yielded usable average household incomes for six provinces from the 1890s and start of the twentieth century. See the Online Appendix, plus the derivations in the Excel File, “Peasant incomes 1904 23mar12.xlsx” at <http://gpih.ucdavis.edu>, under the Russia files.

is believed to have been shared fairly evenly (e. g., Robinson 1972 [1932]).²⁷ Thus far we have two opposing tendencies (suggested by comparing Panels A and B of Figure 1): highly unequal ownership of land among individuals, and relatively equal incomes within the peasantry from their access to collective landholdings. To complete the

²⁷ As noted by Chaianov (1986), the size of peasant communal allotments was often closely linked to the amount of household labor, and so land inequality within the commune was related to the distribution of household size. The 1905 data on allotment land does not provide within-commune information, but the aggregate distributions we derive across communes closely resemble the across-household variation reported in *zemstvo* studies such as Scherbina (1900). Also see Svavitskaia and Svavitskii, eds. (1926), for other land distributions from *zemstvo* research.

picture of overall inequality, we need to add other types of income and then work out the implications of the gaps between the estate classes' average incomes.

Top Incomes (The Opyt' Study)

As in many other states in the late nineteenth and early twentieth centuries, officials in Tsarist Russia began to consider the installation of an income tax to generate revenue (Kotsonis 2004). Using the census as a springboard, the Ministry of Finance launched an inquiry into the structure of top incomes in order to estimate how much income tax revenue the state could potentially raise, and from whom. One fruit of this endeavor was the Ministry's detailed estimates of high incomes over the period 1900 to 1904—*Opyt'* (Russia, Ministerstvo 1906). Targeting only the top of society for potential income taxation, the Ministry's estimates covered those annual incomes exceeding 1,000 rubles. The corresponding total household count came to only 2 percent of all households. A follow-up study in 1910 gave further elaboration of the forecasted possible revenues. Yet in the end, the project for a comprehensive income tax was blocked and remained unimplemented before the 1917 Revolution.²⁸

To exploit this unique data source, we must confront a large problem shared by all the income data from Imperial Russia: official fiscal authorities never measured total income, unlike the micro-level (e.g., *zemstvo*) budget surveys of worker and peasant households. What the *Opyt'* data offer are totals of specific kinds of income in different ranges above 1,000 rubles and the numbers of households receiving income in each source by size category by province cell. While some data in the source offer the distribution of land area or land value, with no attention to other incomes; others are confined to urban real estate rents; other data represent wage and servant income in narrow formal sectors; others cover just industrial or commercial profits; and so forth. The same problem often arises in other countries, e.g., in the separate-schedule income tax data of Victorian Britain, or in early America, where the data on property incomes are completely divorced from the data on a household's own human earnings.

The size of this top group and its different sources of income are summarized in Table 5. Such high incomes were especially concentrated in landownership and commercial enterprises, but they

²⁸ Gorlin (1977) and Kotsonis (2004) summarize the fiscal struggle over tax reform in this period. The Ministry of Finance relied on a large number of published and unpublished data sources to identify top incomes.

TABLE 5
OPYT' ESTIMATES OF HOUSEHOLDS WITH INCOMES ABOVE 1,000 RUBLES, C. 1904

	Totals for Households with Incomes Above 1,000 Rubles in the Given Category			
	Number of Households	Total Income (rubles, 1,000s)	Income per Household	
Land rents	52,764	318,442	6,035	(a)
Urban real estate	46,143	214,270	4,644	(b)
Commercial-industrial enterprise profits	67,170	531,335	7,910	(a)
From financial investments	55,235	239,066	4,328	(c)
State service salaries (1905)	91,204	180,745	1,982	(c)
Urban government	4,521	8,113	1,795	(c)
<i>Zemstvo</i> officials	7,830	12,576	1,606	(c)
Personal productive enterprises	30,144	86,994	2,886	(c)
"Professions"				
Doctors	8,237	30,954	3,758	(c)
Lawyers	4,705	17,564	3,733	(c)
Notaries	1,267	3,850	3,039	(c)
Writers	435	1,769	4,066	(c)
<i>Totals</i> [see notes]	369,655	1,645,680	4,452	

Notes: These data were derived from Russia, Ministerstvo (1906). Each row's counts of persons and incomes refer only to its type of income source. As noted in the text, the officials were unable to combine the different types of incomes for any given household. The comments refer to: (a) = 50 provinces of European Russia, (b) = 49 provinces = European Russia minus Arkhangel'sk, and (c) = unclear geographic coverage, probably the fifty European provinces plus the returns from a few reporting provinces in the North Caucasuses and Transcaucasia, but excluding Finland, Poland, Central Asia, and Siberia. Russia, Ministerstvo (1906), itself, summarized the overall returns at the broader (c) geographic basis. The totals reported in its Table XXIII were thus larger: 404,703 households, with incomes totaling 1,723,779,477 rubles. For details, see the file, "High incomes c1904, from the *Opyt*' (1906) study ...," under Russia in the main data list at <http://gpih.ucdavis.edu>.

were also evident in state service and from returns to financial investments. To understand the distribution of incomes at the very top, we utilize the fact that *Opyt*' breaks down these high-income categories by province and into six different ranges, from the 1,000–2,000 range up to incomes above 50,000 rubles. Again, the original data treat each income source as separate, although it is very likely the case that the highest earning households received more than 1,000 rubles from multiple sources. The details in *Opyt*' illuminate the top of the income structure, once we have made plausible assumptions about how the different sources of income were combined into the same households.

In general, these assumptions mimic our work with the 1905 land statistics, in that combining multiple sources of high incomes for one household necessitates taking one or more sources from another household, and bounds on the impact of such reshuffling can be established.²⁹

RUSSIAN INCOME INEQUALITY C. 1904: RESULTS

We combine information on the number of households by class and sector, the distribution of land, the sources of peasant incomes, wage data, and top incomes from the *Opyt*’ study to map out the distribution of incomes in European Russia around 1904. The underlying sources provide these data at the provincial level, and we take advantage of this to construct geographically disaggregate estimates. We estimate mean incomes accruing to each class/sector “cell,” order the cells. The cells number about 85 per province, or 3,529 nonzero cells for the fifty provinces. We aggregate up to define the relevant income shares and Gini coefficients (this is done both at the provincial level and for all of European Russia). Below, we focus on our intermediate, “preferred” inequality estimates, which assume that each household in a cell has the same mean income.³⁰

Figure 2 reports an intermediate result of this exercise: the estimates of mean incomes across all types of households in each province.³¹ The highest incomes were evident in the Baltic and northwestern provinces (including Petersburg, at 1,317 rubles), in Moscow (1,147 rubles), and in the Black Sea provinces (Kherson, with Odessa, at 829). The Eastern provinces had lower incomes, as did a number of central agricultural provinces. These estimates are consistent with existing studies of Russian living standards (i.e., Mironov 2010, 2012),

²⁹ If all high incomes accrued to the roughly 148,000 households (0.81 percent of all households) that definitely received at least one high income by our calculations (Table 5), the estimated Gini would be close to .400. However, this is surely an overestimation of the increase in the Gini, as these other high incomes were certainly coming from other upper percentiles in the distribution. We provide additional details on robustness exercises along these lines in the Online Appendix.

³⁰ To see concrete examples, consult gpih.ucdavis.edu, Excel file, “Income distributions in European Russia c1904,” Worksheets (1)–(3). Worksheet (1) lists sources. Worksheet (2) illustrates with calculations of total incomes for St. Petersburg nobility, Kherson merchants and *pochetnye*, and Kostroma peasants. Worksheet (3) gives fuller details for all sector/estate combinations.

Our preferred estimates also make particular assumptions about the aggregation of incomes from particular sectors / activities for each social class. We discuss these and provide additional details in the Online Appendix and in the “Russia” files of <http://gpih.ucdavis.edu/>.

³¹ The underlying numbers are available online in the “1904 inequality” file at <http://gpih.ucdavis.edu/>.

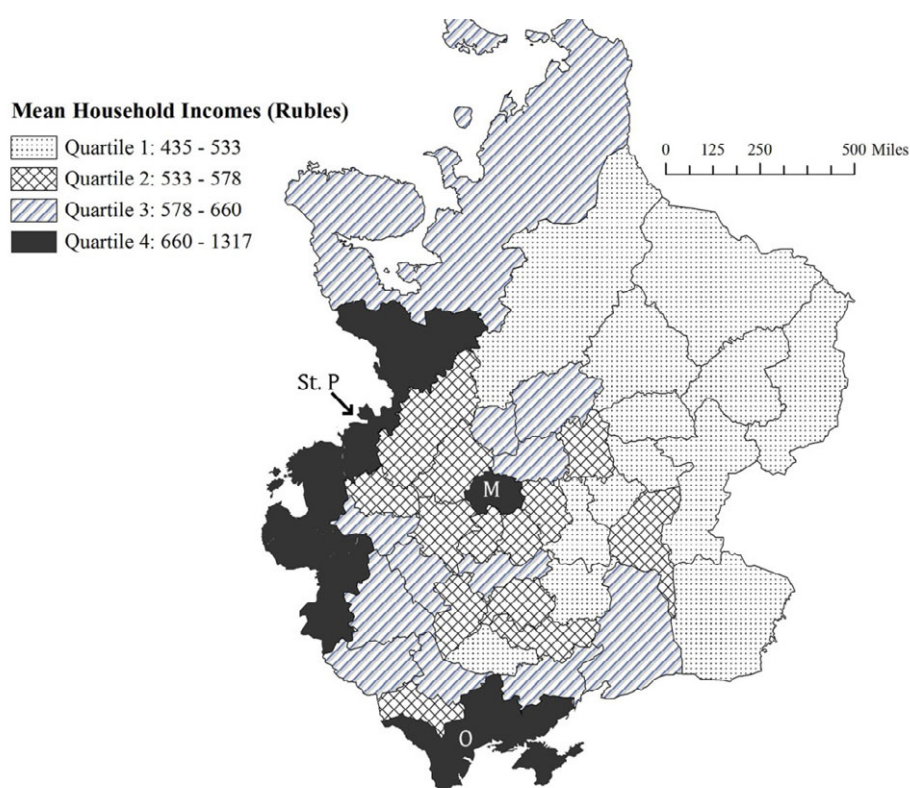

FIGURE 2
THE GEOGRAPHY OF HOUSEHOLD INCOME LEVELS, C. 1904

Note: For sources and the methodology behind the income calculations, see the text.

especially those that emphasize the heterogeneity of economic development by the early twentieth century (Dennison and Nafziger 2013; Wheatcroft 1991). The overall mean income of 612.5 rubles is very close to Gregory's (1982) aggregate per capita income of 100 rubles, with average household size of around six individuals.

We present our preferred estimates of household income inequality in 1904 in Table 6. Our estimate of the top income 1 percent income share (13.5 percent of total income) happens to be close to Gregory's calculation, which relies exclusively on the *Opyt'* data and his national income data (Appendix Table 1).³² The top 20 percent of households

³² As such, Gregory does not document the overall income distribution (by province or in aggregate), which is precisely what we to accomplish. When we aggregate over all households, we come to a total income for the fifty provinces of European Russia of 11.2 billion rubles. This is comparable to Gregory's (1982) estimate of roughly 16.2 billion for the entire empire within

TABLE 6
PREFERRED INCOME INEQUALITY ESTIMATES FOR EUROPEAN RUSSIA, C. 1904

	Income Shares (percent of total income)	Mean Incomes (rubles)
Top 1 percent of households	13.5	8,241.7
Top 5 percent of households	22.7	2,785.4
Top 10 percent of households	31.9	1,953.7
Top 20 percent of households	47.7	1,461.8
Next 40 percent of households	31.0	473.8
Bottom 40 percent of households	21.3	326.2
Gini coefficient	0.362	
	Overall Mean	612.5
	Overall Median	408.5

Notes: These numbers reflect our preferred estimate as described in the text. Data and further details may be found in the text, the Appendices (published and online), and the 1904 inequality file at <http://gpih.ucdavis.edu>.

received slightly less than 50 percent of total income, and median incomes were 2/3 of the mean level. Based on 3,529 populated class/sector/province cells, we estimate the overall Gini coefficient to be approximately 0.36.

Figure 3 reports the geographic heterogeneity of income inequality within each province. These data rely on the same methods for calculating Gini coefficients as we employ in the aggregate in Table 6 but are executed separately using each province's data from the various sources described earlier. In general, the mean income levels reported in Figure 2 are positively correlated with the level of inequality (coefficient of 0.75). The two capital provinces saw high levels of inequality, as Moscow and Petersburg were the only two provinces with Ginis above 0.5. Other provinces with high inequality included the Baltics, southern Ukrainian and Black Sea provinces, and Orenburg in the Urals. The lowest levels of income inequality were generally found in the northern provinces and the upper Volga region.

We place these findings on the Russian income distribution in 1904 into context in the next section. In the meanwhile, it is important to acknowledge four mechanical ways that these "preferred" estimates may underestimate or overestimate the true level of inequality. In each case, we note the errors that may remain, yet we find that the

the much larger USSR borders (therefore, excluding Poland and Finland), which he derives from the production side.

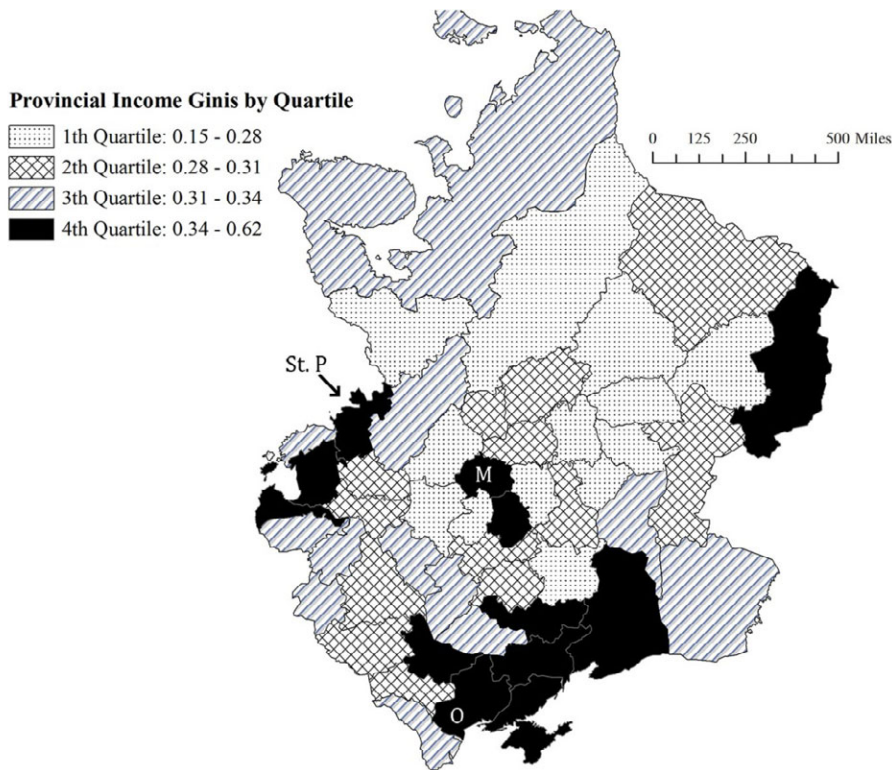

FIGURE 3
THE GEOGRAPHY OF INCOME INEQUALITY, C. 1904

Note: The underlying sources and methodology for calculating income inequality are discussed in the text.

imperfect source materials do deliver enough information so that the true inequalities of income must have been close to our estimates.

A first possible bias relates to multiple land holdings. The available land statistics treat owners in each district as distinct, although we know that the largest landowners in Russia held numerous properties scattered across provinces. However, it turns out that the available data have imposed enough constraints so that their failure to merge properties across provinces is unlikely to lead us to underestimate inequality by very much.³³

A second possible bias may arise from our assumption about the distribution of incomes within the class/sector cells. In our preferred estimates, all of the households in a cell are assigned its mean income, and, by default, we do not assume that incomes overlap across groups. Recent work by Jørgen Modalsli (2011) suggests that this simplifying

³³ For a demonstration of how this constraint is unlikely to generate biased estimates, supported by literature on the top estates, see the Online Appendix.

assumption may not lead to the underestimation of inequality when within-group dispersion takes particular forms, even in studies with only a few dozen cells. Our use of 85 cells for each of fifty provinces suggests that there is little possible bias from using cell means.³⁴

A third possible source of bias may arise from how we assign incomes from other sectors to households whose primary earnings are located in one particular sector. Although peasant, noble, and other types of households tended to cluster in one sector (usually agriculture), these households also earned income from other sources in Russia, as in all other countries. We feel that our preferred estimates make a number of reasonable assumptions regarding this aggregation, especially for the peasantry and other lower income groups.³⁵

Finally, we see only a small bias in overall inequality coming out of the information on top incomes reported in Russia, Ministerstvo, *Opyt'* (1906). One might initially fear that the different kinds of incomes in Table 5, such as rural land or urban real estate or government salaries, all referred to different incomes of the same very rich households, causing an understatement of inequality. Yet here too, as with the land distribution, even flawed data have succeeded in putting bounds on the possible true distribution of income. Common sense and simple algebra confirm that the source materials' separations of different kinds of income do not seriously undermine our results.³⁶

RUSSIAN INEQUALITY IN COMPARATIVE PERSPECTIVE

In the degree of its household income inequality in the early twentieth century, Russia was not alone. So says Table 7's comparisons of two kinds of summary measures of inequality: the shares of all incomes received by the top ranks, and the Gini coefficient. Even though one might have expected that a country on the eve of a large Revolution and, subsequently, the first Communist Revolution would have provoked its fate with some of the world's widest gaps

³⁴ On the inequality effects of income overlap among groups, also see Milanovic, Lindert, and Williamson (2011). The relevant details of our preferred estimates related to this issue are available in the "Income Distribution" file, which is downloadable from <http://gpih.ucdavis.edu>.

³⁵ The file, "Households by estate (soslovie), sector (zanyatie), and province 1904 (Nafziger-Lindert)," available through the Online Appendix, spells out additional details of how we employ the mix of reported occupations to approximate the distribution of labor incomes across sectors.

³⁶ See the Online Appendix. It is worth noting that we do not assign an income to the Tsar's household. Essentially, we are including that income in the residual national income we assign to the state (this is for practical reasons, as the two are often hard to distinguish in the available government budgetary materials). See below for some implications of this approach.

TABLE 7
INCOME INEQUALITY IN IMPERIAL RUSSIA AND SELECT OTHER SETTINGS

	Percent of All Income Received by		Gini Coefficients
	Top 1 Percent	Top 5 Percent

Notes: The Russian estimates are the preferred estimates from Table 6. The main tertiary sources are Atkinson, Piketty, and Saez (2011); Milanovic, Lindert, and Williamson (2011); files available at the Global Price and Income History Group (<http://gpih.ucdavis.edu>, “early income distributions”); and the World Bank’s Deininger-Squire inequality database at http://www.wider.unu.edu/research/Database/en_GB/wiid/.

in income, Table 7 offers no confirmation of this hunch. The clearest contrast consists of a set of experiences where inequality was more severe than it was in Imperial Russia. One such bastion of inequality was Victorian England, as represented by Dudley Baxter's estimates for 1867 (two others were Peru and South Africa, as Table 7 suggests). The gaps were wider in England, both between top incomes and middle incomes and between middle incomes and the bottom.

Another intriguing comparison is with inequality in Russia today.³⁷ Some very rough conclusions are possible, once one considers two data limitations. The first limitation involves differences in geography: the Russian Federation has lost the imperial provinces that have become Belarus, Ukraine, and Moldova, but now includes the Siberian and northern Caucasian parts of the Federation. The other is that the post-Soviet measures of income distribution tell inconsistent stories because of changing definitions of income and population. The most comparable with our estimates for Imperial Russia are the 1995–1998 measures of the distribution of households' gross (pre-tax and pre-transfer) money income by Goskomstat, the predecessor of today's RosStat. Taking the estimates at face value, gross income inequality was already a bit higher in 1997 than in 1904. We suspect that these numbers understate the rise in inequality in the Yeltsin decade by underreporting top incomes.³⁸

Clues about movements in Russia's gross income inequality since the mid-1990s can be gathered from other series, ones that are less directly comparable with our 1904 measure. These other measures suggest a rise in inequality to around the year 2000, followed by equalization since then, not only in Russia but also in Ukraine and Moldova. In Belarus, inequality had already peaked back in 1993, and has drifted

³⁷ Estimates of the distribution of earnings or income showed fluctuating but generally declining levels of inequality over the Soviet period. See Bergson (1984) and the estimates documented in Appendix Table 1 in the Online Appendix.

³⁸ We suspect this, in part, because the 1995–1998 estimates implausibly imply a higher middle-class share at the expense of the top 20 percent and the bottom 40 percent, relative to Imperial Russia, as shown by these income shares:

	Eur. Russia	Russian Federation			
Income share of	1904	1995	1996	1997	1998
top 20 percent of households	47.7	47.1	45.1	46.3	47.0
41–79 percent	31.0	37.4	38.0	36.7	36.0
bottom 40 percent of households	21.3	15.5	16.9	17.0	17.0
Gini coefficient	0.362	0.412	0.385	0.393	0.398

These figures from 1995–1998 are from the Deininger-Squire WIID 2c data set available at http://www.wider.unu.edu/research/Database/en_GB/wiid/. Our Table 7 cites the 1997 Gini to avoid overstating the contrast with 1904, and to avoid highlighting data from the crisis year 1998.

down since then.³⁹ Combining Table 7's direct comparison of 1904 and 1997 with the post-Soviet movements in other series suggests that relative to European Imperial Russia before the Revolutions, the income distribution in the Russian Federation started out less unequal at the time of the collapse of the Soviet Union, then became more unequal by the mid-1990s, reaching one of the highest levels of inequality in all of post-1861 Russian history.⁴⁰

The other settings of high inequality, in which Gini coefficients exceed 0.42, mostly consist of countries in the late twentieth and early twenty-first centuries. Among the many countries where incomes are clearly more unequal today than they were at the sunset of Imperial Russia are Brazil, China, the United States—and possibly Russia itself. All four of these countries have experienced a rise in inequality, the United States since the eighteenth century and the other three during the twentieth. Yet for many other countries, such as Britain and Sweden, the gaps are now narrower—households are more equal—than they were in the nineteenth century and early twentieth.⁴¹

Such conventional comparisons of inequalities in nominal income need to take in account the redistributive role of the state in inequality. The possibility of redistribution from poor to rich, alias “fiscal regressivity,” lurks in the background here. It is hidden by the fact that for Tsarist Russia, as for other countries at the time, the data offer more information on “pre-fisc” income inequality than on the “post-fisc” distribution after taxes and transfers. Relative to other European countries, Russia showed more signs of fiscal regressivity in declining to redistribute from rich to poor. One sign of regressivity in the government's policies is the fact that the net rental values on state and church lands could have been worth as much as 8.1 percent of national income.⁴² If one views these as incomes that an elite withheld from the people who worked those lands, then top-income shares should be

³⁹ See the downloadable estimates from several sources available online at http://www.wider.unu.edu/research/Database/en_GB/wiid/ and the 1989–2009 annual TransmonEE measures available at <http://www.transmonee.org/>.

⁴⁰ We cannot say much about pre-1904 inequality at this point, although it is certainly possible that the trend was downward following emancipation. We hope to investigate this earlier period in future work. Furthermore, the contrast between pre-revolutionary and post-Soviet inequalities may have looked quite different if we were to consider the inequality of *disposable* income, after taking account of taxes and transfer payments. See below for tentative thoughts in this direction.

⁴¹ By 1904 the share of income received by the top one percent of U.S. households was probably already as low as it was in Russia, as was the top one-percent share in Germany (Atkinson, Piketty, and Saez 2011, figure 7B).

⁴² This applies the rental rates of Table 3 to the landholdings of the state and Church in 1905, as documented in Russia, Tsentral'nyi (1905). The original sources are not clear as to whether the Romanov family property is included in state lands or in private (noble) landholdings.

raised by this amount. Another sign of regressivity was that failure to pass an income tax when other governments were doing so in the early twentieth century. This was compounded by the central government's growing reliance on revenues from the indirect taxation of basic consumption goods. By the early twentieth century, central government indirect taxes—generally on goods important to all classes such as salt, sugar, etc.—were more than three times direct property and corporate incomes taxes, and the budgetary numbers on the former did not include the state's control of the alcohol monopoly.⁴³ On the expenditure side, the central government failure to finance education left primary schooling at the mercy of political debates within *zemstva* and other impoverished local governments until limited state-sponsored efforts after 1905.⁴⁴ The failure to redistribute to any significant degree through investments in broad public goods distinguishes the Russian experience from the late nineteenth—early twentieth century emergence of substantial social spending in the more developed economies of Europe and elsewhere (Lindert 2004).

CONCLUSION

Russia's distribution of incomes thus contrasted sharply with the distribution of political voice on the eve of the 1905 Revolution. Russia's inequality of political voice was extreme: Of the 53 sovereign states in 1904, Russia was one of the bottom four having a Polity rating of zero democracy and complete autocracy.⁴⁵

Yet in terms of income inequality, Russia seems to have been relatively egalitarian among data-supplying countries. This income result might be viewed as the net result of two fundamental influences on Russian economic fortunes prior to the Revolutions. The fundamental egalitarian force was geographic: Russia has always stood out as abundant in productive land and staple grains. The land/labor logic that other scholars have used to link the Black Death to the freedom and wellbeing of the English yeoman should theoretically have compressed the income structure—and likely

⁴³ See the breakdown for 1900 and 1913 as summarized in Anfimov and Korelin, eds. (1995, p. 154). On the shift from direct towards indirect central taxation, see Gorlin (1977) and Kotsonis (2004). After 1906 the state did raise corporate income taxes to relatively high levels (more than 10 percent of profits), thus *slightly* decreasing the regressivity of the fiscal structure (Bowman 1993). Although the *zemstvo* did rely on local property taxation for revenues, rates were relatively high on peasant land compared to non-peasant property (Nafziger 2011).

⁴⁴ See the discussions of early twentieth-century local school progress in Russia and other impoverished settings in Chaudhary *et al.* (2012, especially the summary in their table 1).

⁴⁵ The other three were Iran, Thailand, and Ottoman Turkey. The ratings exclude colonies. See <http://systemicpeace.org/polity/polity4.htm>.

continued to do so, other things equal, even on the eve of Revolution. Contemporary accounts of land “scarcity” were not reflected in the statistical evidence and were almost entirely limited to a declining region to the south of Moscow, where agriculture was simply not as productive as the southern and Ukrainian provinces (Wheatcroft 1991). Although the peasantry was not the homogenous group that is often assumed, the predominance of communal property among such a large part of the population likely held down inequality (even if only by providing a security net with which peasants could pursue nonagricultural pursuits).⁴⁶

Yet political inequality also dominated the country’s pre-Revolutionary history. The demise of serfdom did not necessarily end restrictions on peasant labor mobility, nor did it eliminate the economic and political power of the landed elite in the countryside. The imperial autocracy’s dependency on elites for its power continued to be reflected in the property, income, and political inequality among estates and classes. Even if extraordinary political inequality did not manage to create extraordinary income inequality by global standards, it did leave those signs of limited, or even regressive, redistribution we have already noted. Furthermore, income inequality in contemporary Russia likely matches or exceeds the pre-Revolutionary level, and the fiscal structure is perhaps equally skewed towards politically connected elite at the expense of those lower on the income distribution (Gelbach 2008).

The limited, albeit geographically varied, inequality we find is consistent with economic growth and a positive trend in living standards, especially in rural areas. Even if peasants were increasingly “differentiated,” slowly rising agricultural productivity and growing opportunities for nonagricultural earnings were likely improving conditions at the lower end of the income distribution. This process may have been accelerated by the subsequent Stolypin land reforms, which eased constraints on peasant mobility and may have led to improvements in agricultural productivity (Chernina, Dower, and Markevich forthcoming). However, the fact that inequality appears to have been particularly concentrated in the booming capital cities hints at a possible tenuous link to the Revolutions of 1905 and 1917, which both began in these urban settings. Whether the level of income inequality was related to the amount and distribution of subsequent *rural* unrest in the two revolutions is a topic worth further exploration.⁴⁷

⁴⁶ Even nineteenth-century Russian fiction—from Tolstoy’s *War and Peace* to Turgenev’s *Fathers and Sons* and beyond—often emphasized the relatively poor nobleman living amidst an apparently egalitarian peasantry.

⁴⁷ Another topic well worth further exploration is the relationship of rural *land* inequality and the incidence of peasant unrest, given that at least some of the apparent (eventual) rural

The research task that now dominates our agenda is to trace and explain the earlier path to the inequality of the early twentieth century. Was it always that way? Or did the classes' relative fortunes change across the Emancipation Era (between the benchmarks of 1858 and 1877) or the post-Emancipation era, say from 1877 to 1913? What earlier movements were likely? Mironov and others have led the way with important new work on real wages and other indicators of the *level* of living standards, but significant empirical materials remain relatively untapped throughout the long nineteenth century to further explore the *distribution* of economic outcomes. The task is not an easy one for the pre-Emancipation era, mainly because it is hard to capture the income effects of the ownership of serfs.⁴⁸ Further archival and original source research will hopefully allow us to make progress in identifying the dynamics of Russian income inequality, both before and after 1904.

support of the 1917 Revolution revolved around the redistribution of large private properties. While overall land inequality was relatively low due to communal allotments, the potential market power held by private property holders over additional arable land and other complementary agricultural resources may have been associated with greater unrest in certain areas. For a related argument in the Chinese context, see Kung *et al.* (2012).

⁴⁸ Again see Mironov (2000, 2005, 2010, and his data series at <http://gpih.ucdavis.edu>). For the seventeenth century, see the materials collected in Richard Hellie's vast data set on the same web site. The issues regarding the incomes extracted from serfs are well framed and illuminated by Dennison (2006).
